as for the automotive industry, there are more and more examples of automotive brands investing in parallel platforms and systems to minimize the development costs and to facilitate transitions for future vehicles. this development takes various forms, such as a parallel platform for the increased number of electric cars using the same battery pack technology; a modular architecture for electrified and plug-in hybrid vehicles; or a common architecture to exchange information about many vehicles and services. in any case, the automotive industry appears to be moving towards more and more of a platform-based organization. intuitively, this makes sense, as platforms can be seen as a broad community of producers that share common means to achieve competitive advantage, with a clear-cut division of labour. in order to make sure that the new vehicles can be easily integrated into the existing fleets and systems, it is necessary to have a common architecture for the plug-in hybrids, electric vehicles, and so on. this can take the form of a common euro 6 compliant architecture, but it can also be a common architecture to exchange information about many vehicles and services. moreover, it is obvious that in a vehicle-based

platform architecture, the data of the vehicles will have to be plugged in for autonomous driving, advanced driver assistance systems, and so on. but even if this makes sense from a business standpoint, it is not entirely easy to fit this into practice. so far, automakers' plug-in programs have largely been based on a single automaker's own architecture. this goes back to the fact that the plug-in electrified vehicles or, more generally, the vehicles with an advanced powertrain are relatively new for the automobile industry. but in the future, it is obvious that we will see more and more applications of plug-in hybrids, electric vehicles, and so on. a scenario with five different manufacturers all using their own architecture would be a nightmare!
